# Historical Dates of Ice-Affected Flows for 18 Rivers in New England

By Glenn A. Hodgkins, James M. Caldwell and Robert W. Dudley

## ABSTRACT

Historical dates of ice-affected flows for 18 rivers in New England were compiled and are presented in this report. The length of this record for the rivers ranges from 48 to 71 years, with an average of 62 years. The minimum number of days of ice-affected flow in a water year (October 1 to September 30) ranged from zero on three rivers in south-coastal Maine and coastal New Hampshire to 110 on the Allagash River in northern Maine. The maximum number of days of ice-affected flow in a water year ranged from 106 on the Royal River in south-coastal Maine to 171 on the Allagash River in northern Maine. Six streamflow-gaging stations in Maine, New Hampshire, and Vermont had their latest days of ice-affected flow in the spring of 1939.

## INTRODUCTION

Documentation of changes (or lack of changes) in long-term hydrologic data series in New England and other regions of the world are important for various reasons, including validation of global climate models at a regional scale and analysis of the effects of climatic changes on regional ecosystems. River flows in the 20<sup>th</sup> century in the United States were analyzed by Lins and Slack (1999). Historical lake ice-out dates in New England have been reported (Hodgkins and James, 2002) and analyzed (Hodgkins and others, 2002). The annual dates of ice-affected river flows for the six New England States (Maine, New Hampshire, Vermont, Massachusetts, Connecticut, and Rhode Island) have not been well documented.

Historical dates of ice-affected flow were compiled for 18 rivers in New England as part of a larger study to compile and analyze long-term hydroclimatological data in New England. These data are generally available from the 1930's or 1940's through 2000. The historical dates of ice-affected flow were

compiled by analyzing U.S. Geological Survey (USGS) historical data reports (the annual Water-Data Reports and their predecessor Water-Supply Papers, for States in New England) and files. This report, prepared as part of the USGS Global Change Hydrology Program, makes these data easily available to researchers and other interested parties.

This report would not have been possible without the collection, compilation, and archiving of river ice and flow data by many USGS hydrologic technicians and hydrologists over the past century, often under hazardous conditions. Glenn Smith and other USGS employees in Maine and New Hampshire compiled most of the data used in this report.

## EFFECT OF ICE FORMATION ON THE COMPUTATION OF RIVER FLOWS

Some rivers have been gaged by the USGS in New England for more than 100 years. The primary product of USGS streamflow-gaging efforts has been the computation and publication of daily mean river flows. Flows typically are not measured continuously though. Instead, the river height is measured continuously and the flows subsequently computed using a river height/flow relation, usually called a rating curve. The presence of ice in a river channel affects the relation between river height and flow (Rantz and others, 1982); therefore, the presence of ice in rivers has been historically determined and recorded. The following general discussion of river ice and its effect on the computation of river flow is taken from Rantz and others (1982).

The formation of ice in river channels, in particular on control sections (the riffles downstream of a gaging station that often control the river height at the station), affects the river height/flow relation by causing backwater (a higher-than-normal river height for a given flow). This backwater varies with the quan-

tity and nature of the ice, as well as with the flow. Backwater at a gaging station can be caused by anchor ice or by surface ice. Anchor ice is an accumulation of spongy ice or slush adhering to the rocks of a riverbed. Anchor ice is believed to be either (1) frazil ice (ice crystals formed at the water surface where turbulence prevents the ice crystals from coalescing to form sheet ice) that turbulent currents have carried to the riverbed where the ice then adhered to the rocks, or (2) ice that formed as the result of supercooled water finding nucleating agents on the riverbed on which to crystallize. The ice crystals first formed on the rocks act as nucleating agents for the continued growth of the ice mass.

Regardless of how anchor ice forms, it cannot form or exist when the rocks are warmed by shortwave radiation from the sun which penetrates the water. When the morning sun strikes anchor ice that had formed the night before, and the riverbed is warmed by the incoming solar radiation, the anchor ice is released and floats to the surface.

Anchor ice may build up on the riverbed and (or) the control section to the extent that backwater results. The river-height rise starts in late evening or early morning when the ice begins to form and adhere to the rocks and raises the water level. Usually by 10 a.m., the sun has warmed the riverbed sufficiently to release the ice and the river height starts to fall. The distinguishing feature of the “anchor-ice hump” in river height records is that the rise is slow compared to the fall, whereas an actual increase in river flow would cause changes in river height in the opposite sequence, or at least the river height rise would be as rapid as the fall.

The second type of ice that causes backwater at a gaging station is surface ice. With the onset of cold weather, the water in a river gradually is cooled. Along the riverbanks where the water is quiescent and depths usually are very shallow, temperatures reach the freezing point more quickly; ice crystals form on the surface and adhere to the banks, twigs, and projecting rocks, and a thin ice sheet forms. In the absence of nuclei in the open channel on which the ice crystals may form, there may be slight supercooling of the surface layer before any ice crystals are produced.

The ice sheet builds out from the shore as supercooled water, or water carrying ice crystals, impinges on the already-formed shore ice, and the transported or newly formed ice crystals adhere to the sheet. Eventually, an ice sheet forms across the entire river. The

ensuing increase in the thickness of the ice sheet occurs almost entirely at the interface of ice and water. Surface ice, where it is in contact with the river, increases the frictional resistance and the river height will increase for a given flow.

Rises in river height caused by anchor ice are clearly recognizable from continuous river-height records. Rises in river height caused by surface ice are often recognizable from continuous river-height records. Rantz and others (1982) show examples of the effect of ice on river-height records. River-height records are supplemented by visual observations of river ice conditions, river flow measurements, and daily temperature and precipitation records.

The first ice-affected river flows in New England each fall are caused by the first substantial presence of anchor ice and (or) surface ice. The breakup of river ice in the spring, at rivers with complete or nearly complete ice cover, typically is a dramatic event with the ice cover being picked up and transported by medium or high river flows. Days of ice-affected flows each winter, in general, range from continuous or nearly continuous (from the first to last days of ice-affected flows) in far northern New England to intermittent days of ice-affected flows in southern and coastal New England.

## **CONSISTENCY OF DETERMINATION OF DAYS OF ICE-AFFECTED FLOW OVER TIME**

The presence of ice has been determined by the USGS using the same methods from 1913 (and probably before this for several years) to the present (Hoyt, 1913; Rantz and others, 1982), with one known exception. The earliest river-height records in New England typically were collected daily by an observer, rather than by a continuous recorder, until the 1930's. The presence of ice that affects the river height/flow relation, especially anchor ice, may have been interpreted differently using these two methods of data collection. Therefore, for this report, dates of ice-affected flows are reported only for those years when continuous recorders were used at each gaging station.

## **HISTORICAL DATES OF ICE-AFFECTED FLOW**

Records from all gaging stations on rivers in the six New England states (Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont)

(fig. 1) were searched for long-term, usable records. Long-term records are defined as those from a gaging station that was operated for at least 50 years with records through water year 2000. (A water year begins October 1 of the previous calendar year and ends September 30 of the current calendar year. For example, water year 2000 begins October 1, 1999 and ends September 30, 2000.) Usable records are defined as those from a gaging station where its location did not change during the period of record and where flows were not regulated substantially. Ice conditions can be very different in different locations, even a short distance upstream or downstream from any given location. Substantial regulation is defined as regulation that could affect the formation and (or) stability of ice at the station. This condition required that a river at a gaging station either had no known flow regulation over time or an amount of low-flow regulation that was judged to be not substantial. Seven of the 18 rivers considered in this report had some low-flow regulation for all or part of their period of record.

Sixteen gaging stations on rivers in New England met the criteria of this study (tables 1-3, 5, and 7-18). Records from two additional rivers in Maine did not have continuous data up to water year 2000 (Machias River at Whitneyville, Maine and West Branch Union River at Amherst, Maine; tables 4 and 6) but are included in this report because they were compiled for a USGS climate project in coastal Maine (Dudley and Hodgkins, 2002). Data collection at these two rivers was discontinued in the late 1970's. The length of record presented for the 18 rivers in this report ranges from 48 to 71 years, with an average of 62 years.

The reported days of ice-affected flows during periods of missing river-height record at a gaging station can be less accurate than if the river-height record was not missing. Individual years of record, at gaging stations with missing winter river-height record, were censored (tables 1 to 18) if there was any question about the accuracy of the ice-affected flow records. In general, the only acceptable ice-affected flow data in years with missing river-height record were short amounts of missing river-height record at sites with long, continuous periods of ice-affected flows. In these cases, the missing river-height record was not near the beginning or end of the days of ice-affected flow for the winter and there were no substantial peak flows during the period of missing record.

Historical dates of ice-affected flow for 18 rivers in New England are listed in tables 1 through 18. Ice-on in these tables refers to the first day of ice-affected flow for a period of time and ice-off refers to the last day of ice-affected flow for that period of time. A summary of the available data is contained in table 19. All known historical regulation at these sites is listed in tables 1-18. The geographic locations of the 18 gaging stations are shown in figure 1. Most of these rivers are in Maine, with a few in New Hampshire and Vermont. No long-term records were used from Massachusetts, Connecticut, or Rhode Island because no rivers in these states met the criteria of this study.

## **HISTORICAL EXTREMES OF DAYS OF ICE-AFFECTED FLOW**

The earliest dates of ice-affected flows in the fall during the period of record of the gaging stations in this study (tables 1-18, table 19, fig. 1) ranged from October 30<sup>th</sup> on the Piscataquis River in central Maine to November 24<sup>th</sup> on the Royal River in south-coastal Maine. The latest dates of ice-affected flows in the spring ranged from March 26<sup>th</sup> on the Sheepscot River in south-coastal Maine to May 5<sup>th</sup> on the Allagash River in northern Maine. The minimum number of days of ice-affected flow in a water year ranged from zero on three rivers in south-coastal Maine and coastal New Hampshire to 110 on the Allagash River in northern Maine. The maximum number of days of ice-affected flow in a water year ranged from 106 on the Royal River in south-coastal Maine to 171 on the Allagash River in northern Maine.

Three or more gaging stations experienced extreme dates of ice-affected flow in specific water years. The earliest dates of ice-affected flow in the fall, during the period of record of three gaging stations in New Hampshire and Vermont, were in 1971. Six gaging stations in Maine, New Hampshire, and Vermont had their latest spring dates of ice-affected flow in 1939, whereas three gaging stations in northern Maine and northern New Hampshire had their latest dates in 1943. Three gaging stations in Maine and New Hampshire had their lowest number of annual days of ice-affected flows in 1999. Four stations in northern and central Maine had their highest number of days in 1943, three stations in Maine and New Hampshire had their highest number of days in 1956, and three stations in northern New England had their highest number of days in 1972.

**Table 6.** Annual periods of ice-affected flows for 01023000 West Branch Union River at Amherst, Maine

**LOCATION.**--Lat 44°50'25", long 68°22'22", Hancock County, on right bank 200 feet upstream from site of old tannery dam, 0.6 miles upstream from Indian Camp Brook, and 0.7 miles northwest of Amherst (fig. 1).

**DRAINAGE AREA.**--148 square miles.

**PERIOD OF RECORD.**--Methods of data collection considered consistent water years 1930 - 1979.

**REGULATION.**--None known water years 1930 - 1979.

**EXTREMES FOR PERIOD OF RECORD.**--Earliest date of ice-affected flow, November 15, 1933 and 1936; latest date of ice-affected flow, April 9, 1939; minimum number of days of ice-affected flow, 22, 1958; maximum number of days of ice-affected flow, 137, 1934.

Water year	Ice on	Ice off	Ice on	Ice off	Ice on	Ice off	Ice on	Ice off

**Table 7.** Annual periods of ice-affected flows for 01031500 Piscataquis River near Dover-Foxcroft, Maine

**LOCATION.**--Lat 45°10'31", long 69°18'55", Piscataquis County, on left bank 30 feet downstream from Lows Bridge, 1.0 mile upstream from Black Stream, and 4.7 miles upstream from Dover-Foxcroft (fig. 1).

**DRAINAGE AREA.**--298 square miles.

**PERIOD OF RECORD.**--Methods of data collection considered consistent water years 1931 - 2000.

**REGULATION.**--Low-water flow regulated by operation of power plants, water years 1931 - 1965. Regulation unknown, water years 1966 - 1984. Low flows may have been regulated by operation of power plant upstream, water years 1985 - 2000.

**EXTREMES FOR PERIOD OF RECORD.**--Earliest date of ice-affected flow, October 30, 1977; latest date of ice-affected flow, April 25, 1939; minimum number of days of ice-affected flow, 34, 1983; maximum number of days of ice-affected flow, 143, 1972.

**ABBREVIATIONS.**--c, data censored.

**Table 8.** Annual periods of ice-affected flows for 01038000 Sheepscot River at North Whitefield, Maine

**LOCATION.**--Lat 44°13'23", long 69°35'38", Lincoln County, on left bank 50 feet upstream from highway bridge on State Route 126 at North Whitefield, at mouth of Finn Brook, and 0.3 miles east of North Whitefield village (fig. 1).

**DRAINAGE AREA.**--145 square miles.

**PERIOD OF RECORD.**--Methods of data collection considered consistent water years 1939 - 2000.

**REGULATION.**--Some regulation at low flows, water years 1939 - 1947 by sawmills at North Whitefield and Coopers Mills. Some regulation at low flows by sawmill at North Whitefield, water years 1948 - 1986. No known regulation water years 1987 - 2000.

**EXTREMES FOR PERIOD OF RECORD.**--Earliest date of ice-affected flow, November 22, 1972; latest date of ice-affected flow, March 26, 1956; minimum number of days of ice-affected flow, 0, 1999; maximum number of days of ice-affected flow, 113, 1948.

**ABBREVIATIONS.**--c, data censored.

**Table 12.** Annual periods of ice-affected flows for 01060000 Royal River at Yarmouth, Maine

**LOCATION.**--Lat 43°47'57", long 70°10'45", Cumberland County, on right bank 150 feet upstream from East Main Street bridge in Yarmouth (fig. 1).

**DRAINAGE AREA.**--141 square miles.

**PERIOD OF RECORD.**--Methods of data collection considered consistent water years 1950 - 2000.

**REGULATION.**--Some diurnal fluctuation at low flows caused by mill above station, water years 1950 - 1985. Low flows may have been regulated by operation of mills upstream, water years 1986 - 2000.

**EXTREMES FOR PERIOD OF RECORD.**--Earliest date of ice-affected flow, November 24, 1989; latest date of ice-affected flow, April 2, 1964; minimum number of days of ice-affected flow, 0, 1976; maximum number of days of ice-affected flow, 106, 1987.

**ABBREVIATIONS.**--c, data censored.

**Table 18.** Annual periods of ice-affected flows for 04293500 Missisquoi River at East Berkshire, Vermont

**LOCATION.**--Lat 44°57'36", long 72°41'49", Franklin County, on left bank, 0.4 miles upstream of State Highway 105 bridge, 1.9 miles north of intersection of State Highways 105 and 118 in East Berkshire, 1.9 miles upstream from Trout River, 2.6 miles southwest of Town Hall in Richford, and 3.6 miles downstream from North Branch (fig. 1).

**DRAINAGE AREA.**--479 square miles.

**PERIOD OF RECORD.**--Methods of data collection considered consistent water years 1934 - 2000.

**REGULATION.**--Possible slight regulation at low flows water years 1934 - 2000.

**EXTREMES FOR PERIOD OF RECORD.**--Earliest date of ice-affected flow, November 14, 1939 and 1971; latest date of ice-affected flow, April 19, 1939; minimum number of days of ice-affected flow, 69, 2000; maximum number of days of ice-affected flow, 149, 1972.

**ABBREVIATIONS.**--c, data censored; m, data missing.
